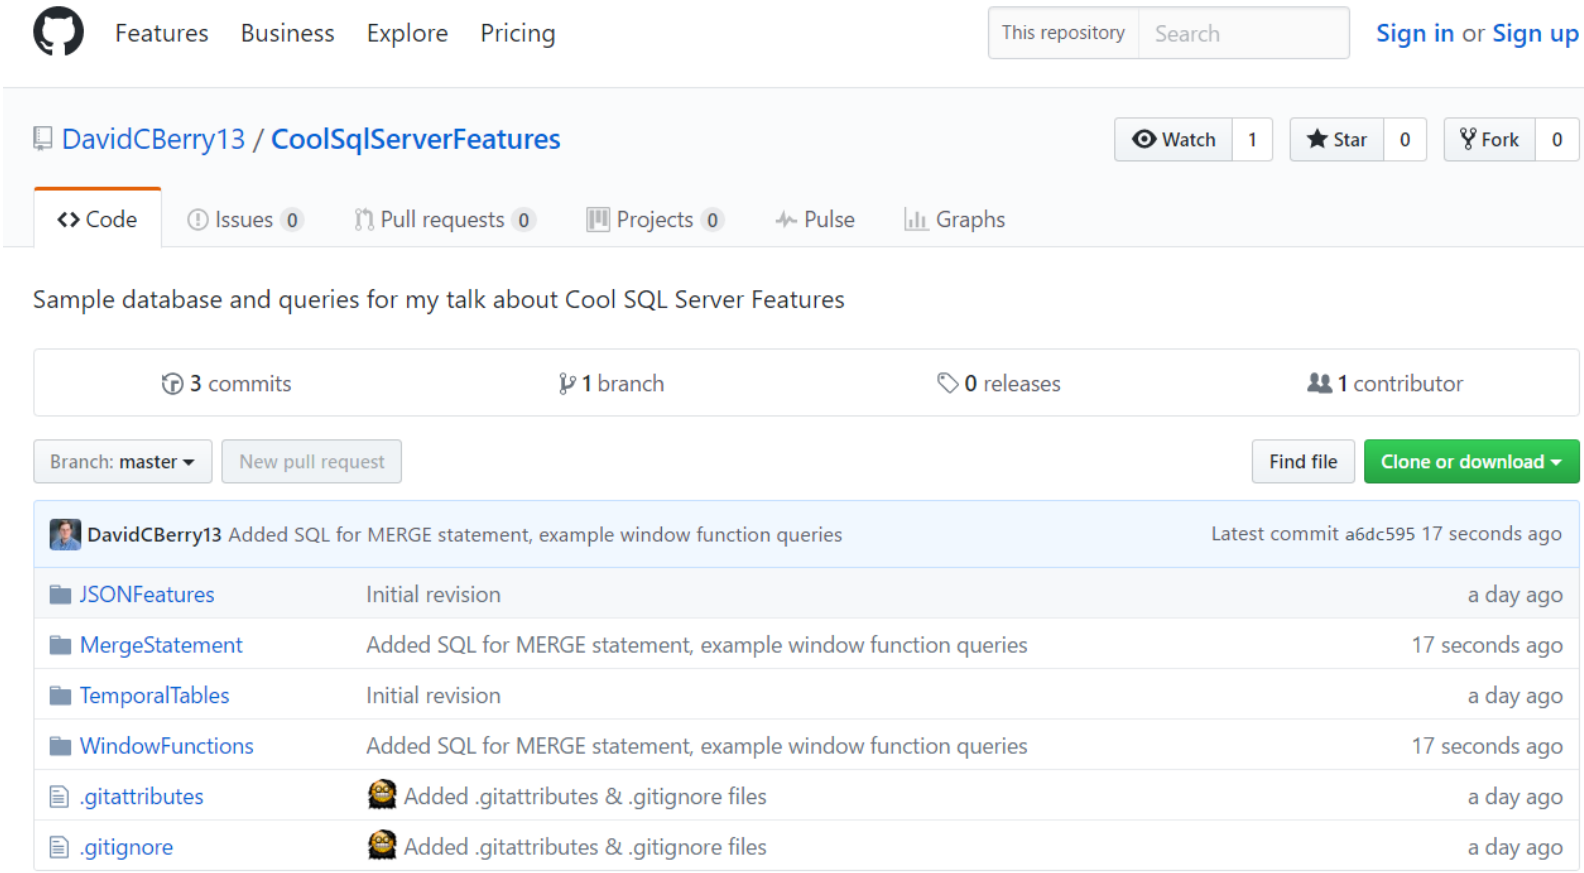
Cool SQL Server Features For Developers

David Berry
@DavidCBerry13
http://buildingbettersoftware.blogspot.com/

Sample Database and Code



https://github.com/DavidCBerry13/CoolSqlServerFeatures/

We all use SQL Server every day...

…we might as well be good at it.

Agenda

MERGE Statement

Temporal Tables

JSON Support

Window (Analytic) Functions

MERGE Statement

Available in SQL Server 2008 and later, SQL Azure

Essentially provides and “UPSERT” capability

Useful when doing bulk updates to tables

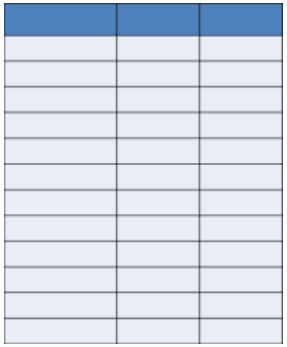
Can be useful for setting reference data in DEV databases

Problem Scenario

Data File

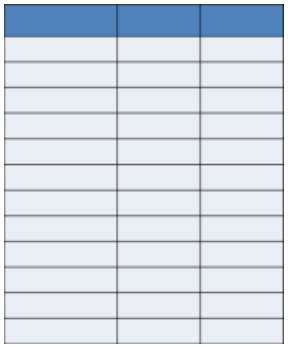
*May contain records already in our data table

Staging Table



Use a MERGE statement to perform an UPSERT

Data Table



MERGE Statement Syntax

```
MERGE INTO Customers AS Target
USING (
    SELECT
    CustomerId,
    FirstName,
    LastName,
    DateOfBirth,
    PhoneNumber,
    Email
FROM CustomersStaging
) AS Staging
ON (Staging.CustomerId = Target.CustomerId)
    WHEN MATCHED THEN
        UPDATE SET
        FirstName = Staging.FirstName,
        LastName = Staging.LastName,
        DateOfBirth = Staging.DateOfBirth,
        PhoneNumber = Staging.PhoneNumber,
        Email = Staging.Email
    WHEN NOT MATCHED BY Target THEN
        INSERT (CustomerId, FirstName, LastName, DateOfBirth, PhoneNumber, Email)
          VALUES (CustomerId, FirstName, LastName, DateOfBirth, PhoneNumber, Email);
--WHEN NOT MATCHED BY Staging THEN
--    DELETE;
```

Using MERGE to Set Reference Data

```
MERGE INTO ProductTypes As Target
USING (VALUES
    (1,  'Laptops',          'Computers'),
    (2,  'Desktops',         'Computers'),
    (3,  'Displays',         'Accessories'),
    (4,  'PC Accessories',   ,Accessories'),
    (5,  'Tablets',          ,Mobile Devices')
)
AS Source (ProductTypeId, ProductTypeName, CategoryName)
ON (Target. ProductTypeId = Source. ProductTypeId )
    WHEN MATCHED THEN
        UPDATE SET
            ProductTypeName = Source. ProductTypeName,
            CategoryName = Source.CategoryName
    WHEN NOT MATCHED BY TARGET THEN
        INSERT (ProductTypeId, ProductTypeName, CategoryName)
        VALUES (ProductTypeId, ProductTypeName, CategoryName)
    WHEN NOT MATCHED BY SOURCE THEN
        DELETE;
```

Temporal Tables

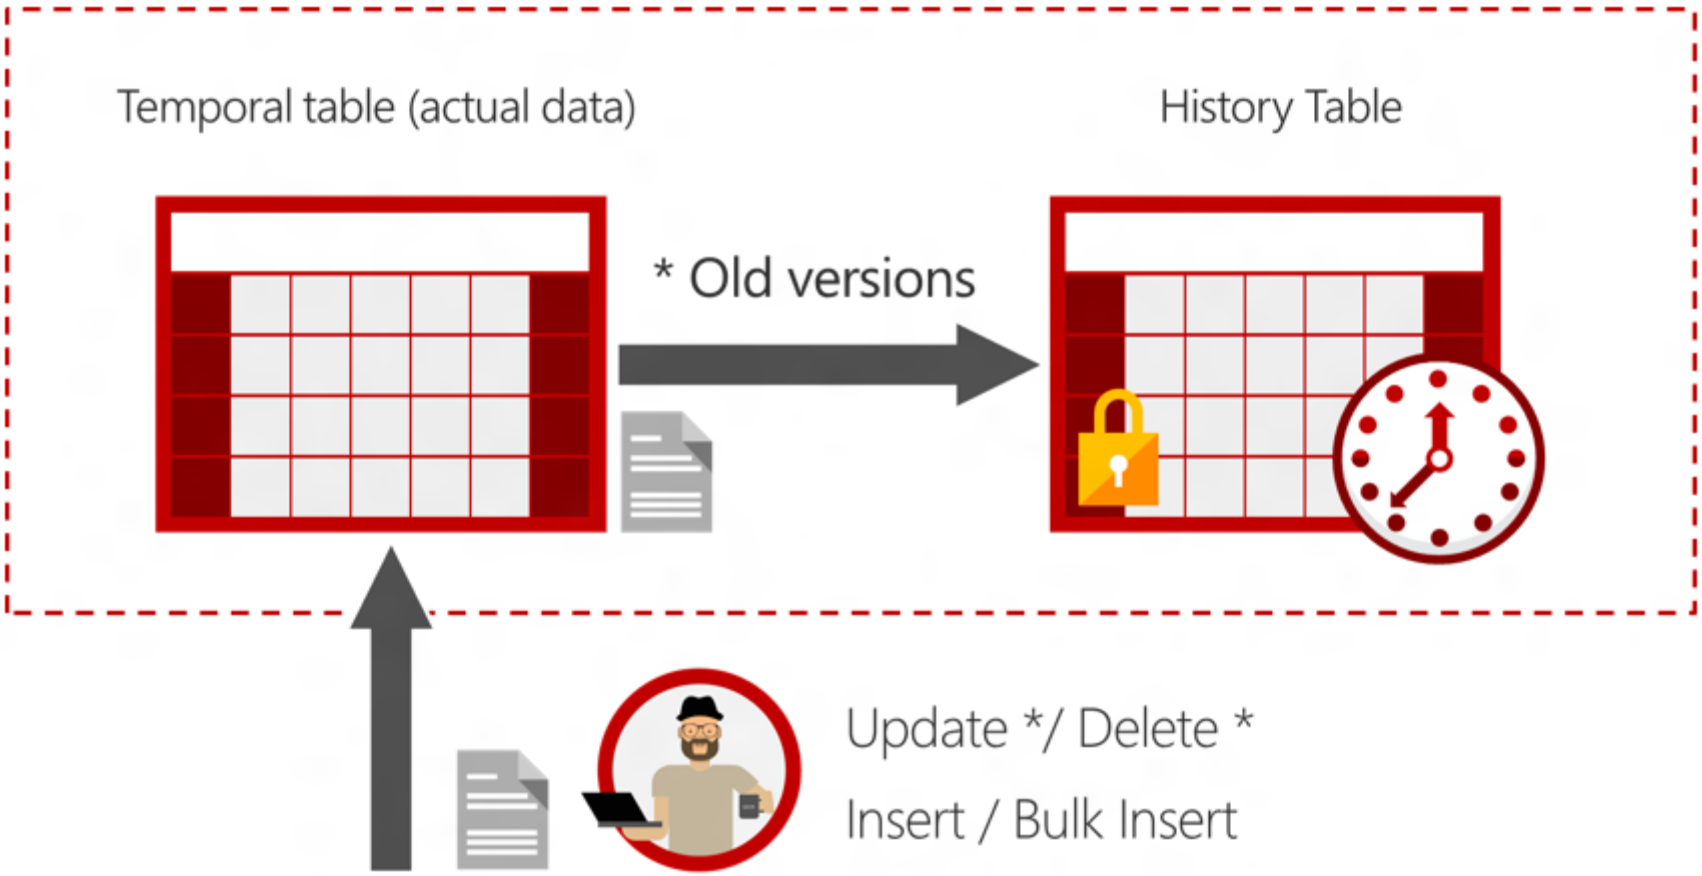
Available in SQL Server 2016, SQL Azure

Every time a row is changed, SQL Server keeps a snapshot of the old row values

SQL constructs allow us to see what the value was at any given date/time

No need to implement your own triggers, history tables and views

Temporal Table Concept



https://docs.microsoft.com/en-us/sql/relational-databases/tables/temporal-tables

CREATE TABLE Syntax

```
CREATE TABLE Contacts
(
    ContactID        INT IDENTITY(1,1)      NOT NULL,
    FirstName        VARCHAR(30)            NOT NULL,
    LastName         VARCHAR(30)            NOT NULL,
    CompanyName      VARCHAR(30)            NULL,
    PhoneNumber      VARCHAR(20)            NULL,
    Email            VARCHAR(50)            NULL,
    ValidFrom        DATETIME2(3) GENERATED ALWAYS AS ROW START,
    ValidTo          DATETIME2(3) GENERATED ALWAYS AS ROW END,
    PERIOD FOR SYSTEM_TIME (ValidFrom, ValidTo),
    CONSTRAINT PK_Contacts PRIMARY KEY (ContactId)
)
WITH (SYSTEM_VERSIONING = ON
    (HISTORY_TABLE = dbo.ContactsHistory));
```

Hiding ValidFrom and ValidTo Columns

```
-- Hide the ValidFrom and ValidTo columns
ALTER TABLE Contacts
   ALTER COLUMN ValidFrom ADD HIDDEN;

ALTER TABLE Contacts
   ALTER COLUMN ValidTo ADD HIDDEN;

-- Show the ValidFrom and ValidTo Columns
ALTER TABLE Contacts
   ALTER COLUMN ValidFrom DROP HIDDEN;

ALTER TABLE Contacts
   ALTER COLUMN ValidTo DROP HIDDEN;
```

Temporal Table Query Qualifiers

Expression	Description
AS OF <date time>	Gets all of the rows that were active at the specified date and time
FROM <start time> TO <end time>	Gets all of the rows that were active at any point during the specified time period, excluding rows that were only active at the start time or end time
BETWEEN <start time> AND <end time>	Gets all rows active in the time period including rows that became active at the ending time of the period
CONTAINED IN (<start time>, <end time>)	Gets all rows that were opened and closed in the period specified
ALL	Get all rows in the table and the history table

JSON Support

Available in SQL Server 2016, SQL Azure

JSON data stored in a VARCHAR data type

Functions available to interact with JSON data

Allows us to mix relational and NoSQL data models in the same database

Storing JSON in Tables

```
CREATE TABLE WeatherDataJson
(
    ObservationId     INT IDENTITY(1,1)  NOT NULL,
    StationCode       VARCHAR(10)        NOT NULL,
    City              VARCHAR(30)        NOT NULL,
    State             VARCHAR(2)         NOT NULL,
    ObservationDate   DATETIME           NOT NULL,
    ObservationData   VARCHAR(4000)      NOT NULL,
    CONSTRAINT PK_WeatherDataJson
        PRIMARY KEY (ObservationId)
);
```

Exposing JSON Values With Computed Columns

```
ALTER TABLE WeatherDataJson
  ADD Temperature AS
    (JSON_VALUE(ObservationData,'$.dryBulbFarenheit'));
```

Getting Data From a JSON Column

JSON_VALUE	Extract a scalar value from a JSON String
JSON_QUERY	Extract an object or an array from a JSON String
OPENJSON	Table value function used for parsing JSON and returning a rowset view of the data

Resturn Results As JSON

```
SELECT
        s.StationCode,
        s.City,
        s.State,
        observations.ObservationDate,
        observations.DryBulbFarenheit As Temperature,
        observations.RelativeHumidity,
        observations.WindDirection,
        observations.WindSpeed
    FROM WeatherStations s
    INNER JOIN WeatherObservations observations
        ON s.StationCode = observations.StationCode
    WHERE
        observations.ObservationDate > '2016-06-01'
        AND observations.ObservationDate < '2016-06-07'
    FOR JSON AUTO;
```

Column or alias names used for property names

Alias used as name of child object

Window Functions

Available in SQL Server 2008 and later, SQL Azure

Extended functionality over traditional GROUP BY queries

Can partition and aggregate data by different criteria in the same statement

Greatly enhances reporting capabilities in SQL Server

Window Function Syntax

```
SELECT DISTINCT
    City,
    State
    CONVERT(DATE, ObservationDate) AS SummaryDate,
    RANK()
        OVER (PARTITION BY City, State, CONVERT(DATE, ObservationDate)
        ORDER BY DailyHighTemp DESC) As HighTemp
FROM DailyWeatherSummaries o
WHERE
    State = 'WI'
      AND ObservationDate BETWEEN '2016-05-01' AND '2016-06-01';
```

PARTITION BY Splits the result set into different partitions or groups using these columns

ORDER BY Orders the rows within each partition for functions where order is important (not used in for some functions)

Window Function Grouping

```
RANK()
    OVER (PARTITION BY City, State, CONVERT(DATE, ObservationDate)
    ORDER BY DailyHighTemp DESC) As HighTemp
```

City	State	SummaryDate	DailyHighTemp	Rank()
Chicago	IL	2017-06-01	65	1
Chicago	IL	2017-06-01	63	2
Chicago	IL	2017-06-01	62	3
Chicago	IL	2017-06-02	67	1
Chicago	IL	2017-06-02	65	2
Chicago	IL	2017-06-02	63	3
Milwaukee	WI	2017-06-01	71	1
Milwaukee	WI	2017-06-01	70	2
Milwaukee	WI	2017-06-01	68	3

Partition Group

Partition Group

Partition Group

Sort Column

Ranking Window Functions

ROW_NUMBER()	Creates sequential number of a row within a partition of a result set, starting at 1 for the first row in each partition
RANK()	Returns the rank of each row within the partition of a result set. If there two or more values tie for a rank, then there will be a gap to the next ranking
DENSE_RANK()	Returns the rank of each row within the partition of a result set without any gaps between rankings in event of multiple values for the same rank
NTILE(<integer>)	Distributes the rows in the partition into the specified number of buckets (groups) and shows what bucket that row falls in.

Analytic Window Functions

FIRST_VALUE(<column>)	Returns the first value of the partition as sorted by the ORDER BY clause
LAST_VALUE(<column>)	Returns the last value of the partition as sorted by the ORDER BY clause
LAG(<column>, <offset>, <default>)	Returns the preceding value in the partition. Offset (optional) allows you to reach back multiple rows. Default (optional) allows a default value to be specified
LEAD(<column>, <offset>, <default>)	Returns the next value in the partition. Offset (optional) allows you to reach forward multiple rows. Default (optional) allows a default value to be specified
